Ransomware cases

Distribution of attacks by duration depending on the initial vector

Initial attack vector		Hours	Weeks	Months	Grand Total
	Exploitation of public-facing applications	12.5%	0.0%	25.0%	37.5%
1. Alexandre	Malicious email	0.0%	0.0%	25.0%	25.0%
J	Compromised accounts	12.5%	12.5%	12.5%	37.5%
*	Grand Total	25.0%	12.5%	62.5%	100%

According to the research data during attacks associated with ransomware, the same basic methods that are inherent in other types of attacks were used as the initial attack vector. Exploiting vulnerabilities and previously compromised user accounts were used in **37.5%** of cases, while malicious mail was used in every fourth case with cryptors.

However, in a number of attacks, the adversary's goal was not extortion or data encryption, but company data, personal data, intellectual property, and other sensitive information. Managing the damage from these kinds of attacks is almost impossible. It leads to reputational loss as well as potential penalties from regulators and lawsuits. All this is used as an additional incentive for blackmail.

We observed data leakage in 10% of cases with cryptors. In addition, the purpose of using cryptors is sometimes to hide the initial traces of an attack and complicate incident investigations. Analyzing the duration of attacks with cryptors, it can be concluded that a significant period of time passes between the initial compromise of the network and the final stage of the attack. In **62.5%** of attacks, attackers spend more than a month inside the network before encrypting data. A properly organized process of attack detection and response reduces the time it takes to detect attackers in the network and prevent final damage.

After the initial penetration, attackers use PowerShell to collect data, Mimikatz to escalate privileges, PsExec to execute commands remotely or frameworks like Cobalt Strike for all stages of attack.

Vulnerability Exploitation

In all cases when exploiting vulnerabilities was used as the initial vector, the main damage is data encryption.

The most prevalent vulnerability in our data set is the CVE-2021-26855 Microsoft Exchange SSRF vulnerability in Microsoft Exchange Server which allows attackers to send arbitrary HTTP requests and authenticate as the Exchange server (used by Hafnium group). It was exploited in 22.7% of cases when vulnerabilities were used. Despite the fact that the protection measures against this attack vector are straightforward - security update, 1-day vulnerabilities are far ahead of other methods of initial penetration.

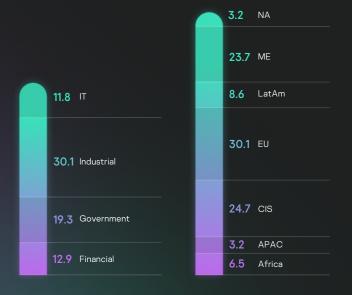

2021 Incident Response Overview

And Experts' Recommendations

Threat intelligence view	reat intelligence view 🖉		Response statistics are based on IR retainer and emergency cases from 2021						
Initial at	tack vecto	or —							
Implement a robust password policy and multifactor authentication	53.6%	53.6 % Exploitation of public-facing applications							
2 Remove management ports from public access									
3 Set zero-tolerance policy to patch management or compensation measures for public-facing applications	14.3%	% Malicious email							
Ensure employees maintain a high level of security awareness	17.9 %	17.9% Compromised accounts							
Implement rules for detection of pervasive tools used by adversaries	Move around and get things done In 39.7 % of all cases, legitimate tools were used								
6 Employ a security toolstack with EDR-like telemetry									
Constantly test reaction times of security operations with offensive exercises	9.7 % Cobalt S	Strike	9.7 % Mimikatz	8.6% PowerShell	10.8 PsExec				
Ensure employees maintain a high level of security awareness									
Back up your data	Rock up your data								
 Work with an Incident Response Retainer partner to address incidents with fast SLAs 	16.0% Data leakage								
Continuously train your incident response team to maintain their expertise and stay up to speed with the changing threat landscape	51.9% Files encrypted								
12 Implement strict security programs for applications with Personally Identifiable Information	11.1%	Activ	e Directory cor	npromised

Introduction

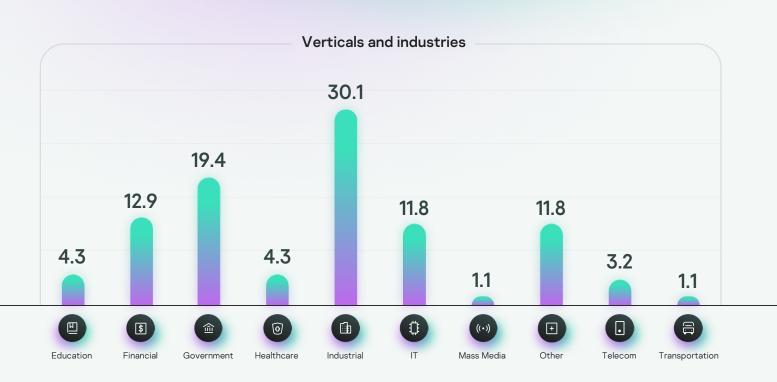

The Incident Response Analyst Report provides insights into incident investigation services conducted by Kaspersky in 2021. We deliver a range of services to help organizations when they are in need: incident response, digital forensics and malware analysis. Data in the report comes from our daily practices with organizations seeking assistance with full-blown incident response or complimentary expert activities for their internal incident response teams.¹ In 2021, although the main threat trends remained, our service approach moved to near-complete - 98% of all cases - remote delivery. Kaspersky Digital Forensics and Incident Response operations are handled by our Global Emergency Response Team (GERT)² with experts in Europe, Asia, South and North America, the Middle East and Africa.

In 2020, the COVID-19 pandemic forced companies to restructure their information security practices to accommodate remote working.

Why incident response is so critical

Ransomware is overtaking money theft and other impacts as a more convenient monetization scheme with much broader industry coverage (not just financial). We can confidently classify most incidents with causes before impact (suspicious events, tool alerts, etc.) as ransomware.

> True positives

For many years, ransomware attacks have retained a dominant role in the cybersecurity threat landscape. We urge you to get up-to-date and actionable information about ransomware attacks from our <u>publications</u> and <u>NoRansom project</u>.

📱 Data leakage

1.3% Malicious e

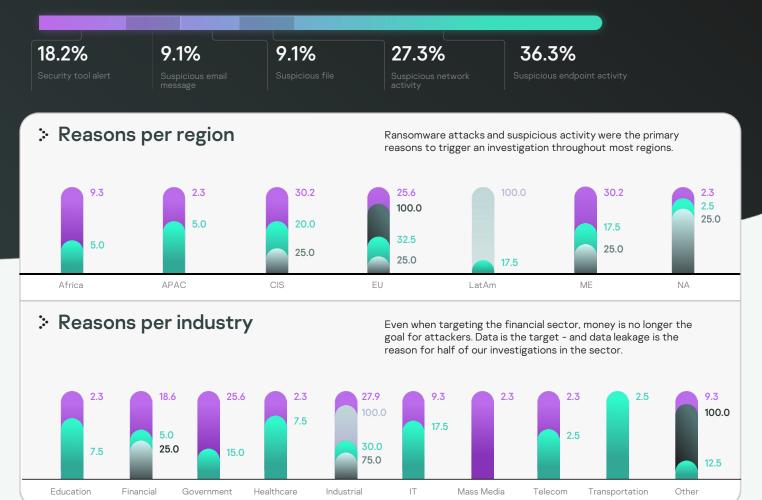

ail Fil

50.6% Files encrypted

1.3% Money theft **41.7%** Suspicious acti

> False positives

12.9% of all incident response requests were for false alarms. Suspicious activity³ reported by network sensors (NIDS, firewall) and endpoint protection (EPP) generate the most false positives. Every second request based on suspicious activity from a network sensor or endpoint was a false positive. Data leakage false positive cases are usually duplicates or leaks from a different organization.

Initial vectors

> Or how attackers get in

Year after year, security issues with passwords, software vulnerabilities and social engineering combine into an overwhelming majority of initial access vectors⁴ during attacks. Setting up and controlling a password policy, patch management and employee awareness along with antiphishing measures significantly minimize the capabilities of external attackers. When attackers prepare their malicious campaign, they want to find low-hanging fruit like public servers with well-known vulnerabilities and known exploits.

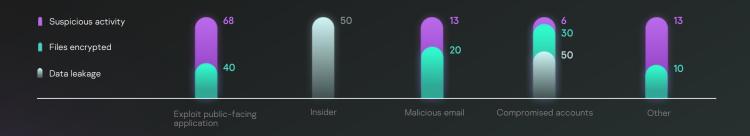

Implementing an appropriate patch management policy alone will reduce the likelihood of becoming a victim by 50%.

In 2021, vulnerabilities were discovered in MS Exchange. Because of Exchange's ubiquitous nature and publicly available exploits for these vulnerabilities, the result is a huge number of related incidents.

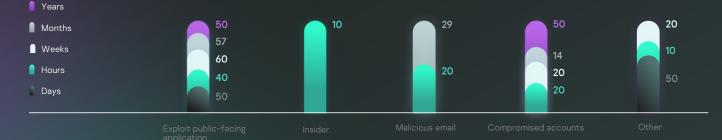

Top initial compromise vectors, and how incidents were detected

Ransomware adversaries use almost all widespread initial access scenarios. Many attacks start with already compromised known credentials, and it's not possible to investigate how they were leaked.

How long the attack went unnoticed, and the top initial vectors

Most of the cases where initial access wasn't identified lasted for more than a year before being detected by the organization, by which time no artefacts were left to analyze due to log rotation policies. More than half of all attacks that started with malicious e-mails, stolen credentials and external application exploitation were detected in hours or days.

4. We identified the initial vector of attack for 30% of cases. Very old incidents, unavailable logs, (un)intentional evidence destruction by victim organization, and supply-chain attacks are among the numerous reasons not to reveal how adversaries initially gained a foothold into the network

Tools and exploits

40.0%

of all incidents were tied to tools

Almost half of all incident cases included the usage of **existing OS tools** (like Lolbins)⁵, well known offensive tools from github (e.g. Mimikatz, AdFind, Masscan) and specialized commercial frameworks (Cobalt Strike).

Because it's very hard to detect these with traditional security controls, another approach is required. Kaspersky Managed Detection and Response detects the usage of such software. Distribution and frequency of tools inside incident cases

Cobalt Strike, Mimikatz, PowerShell, PsExec
